Country Data Contributors

We very much appreciate the long-term co-operation with all national delegates of the IEA SHC Executive Committee, Pedro Dias from Solar Heat Europe and other national experts, who provide the updated solar thermal market data from 70 countries around the globe every year. All these contributors are listed in the Appendix of this report.

Advice and Proofreading

Last but not least, the authors would like to thank Pamela Murphy, Secretariat of the IEA SHC Technology Collaboration Programme for her feedback, ideas for improvement and proofreading of the report.

Background

The Solar Heat Worldwide report has been published annually since 2005 within the framework of the Solar Heating and Cooling Technology Collaboration Programme (SHC TCP) of the International Energy Agency (IEA).

The goal of the report is to: 1) give an overview of the general trends. 2) highlight special applications and outstanding projects, 3) document the solar thermal capacity installed in the important markets worldwide, and 4) ascertain the contribution of solar thermal systems to the supply of energy and the CO_2 emissions avoided as a result of operating these systems.

The collector types detailed in the report are unglazed collectors, glazed flat-plate collectors (FPC) and evacuated tube collectors (ETC) with water as the energy carrier, as well as glazed and unglazed air collectors.

Photovoltaic Thermal (PVT) collectors are included, as the market for these types of collectors has grown in market relevance in recent years. PVT collectors convert solar radiation into both electricity and heat and thus will play an important role in the energy supply of the future.

The report's data was collected through a survey of the national delegates of the SHC TCP Executive Committee, Solar Heat Europe and national experts active in the field of solar thermal energy. As some of the 70 countries included in this report have very detailed statistics and others have only estimates from experts, the data was checked for its plausibility on the basis of various publications.

The collector area, also referenced as the installed capacity, served as the basis for estimating the contributions of solar thermal systems to the energy supply and reductions of CO_2 emissions.

The report's 2022 edition and all past issues can be downloaded from the following website: http://www.iea-shc.org/solar-heat-worldwide

Summary

This report is split into three parts. The first part (Chapters 3 - 4) gives an overview of the global solar thermal market development in 2021. In addition, general trends are described and detailed 2021 data on successful applications, such as solar assisted district heating, solar heat for industrial processes and hybrid photovoltaic thermal systems, are documented.

The second part (Chapters 5 - 7) presents detailed market figures for 2020 from the 70 surveyed countries. In addition to the data from 68 countries documented in previous years, data from Bhutan and Kenya are new additions to this year's report. These chapters include the installed collector area, the distribution of the collectors across various systems and applications and the solar yields and avoided emissions.

The third part (chapter 8) documents the methodological approach, reference systems, climate and population data, literature references and data sources.

Global solar thermal market developments in 2021

The cumulated solar thermal capacity in operation at the end of 2021 was 522 GW_{th} , corresponding to 746 million square meters of collector area. This represents a net increase of 21 GW_{th} or 31 million square meters of collector area in 2021.

The worldwide solar thermal **market increased by 3% in 2021** compared to 2020.

The annual solar thermal energy yield amounted to 425 TWh, which correlates to savings of 45.7 million tons of oil and 147.5 million tons of CO_2 .

Large-scale solar heating systems for district heating or residential, commercial and public buildings

In 2021, 44 new large-scale solar heating systems (>350 kW_{th}, 500 m²) with a capacity of 142 MW_{th} were built. Twenty of these systems were installed in China and 14 in Europe, including one extension, seven in Turkey and three in Mexico.

The three largest of these systems were the solar district heating system in Præstø, Denmark, with a capacity of 5.6 MW_{th}, as well as the Nahwärme Friesach in Austria and the system in Mühlhausen, Germany, both with a capacity of 4.0 MW_{th}.

Photo: GREENoneTEC Solar Industry

By the end of 2021, 530 large-scale documented solar thermal systems were in operation. The total installed capacity of these systems equaled 1,970 MW_{th} , corresponding to 2.8 million m² collector area.

Solar heat for industrial processes (SHIP)

Seventy-eight new SHIP plants with a collector area of 51,539 m² (36 MWth) were documented in 2021 worldwide. With this, the number of SHIP projects in operation adds up to at least 975 systems with an overall installed collector area of 1.23 million m².

Photovoltaic-Thermal (PVT) collectors

The market for PVT collectors and systems saw significant global growth of 13% in 2021. At least 6,036 new PVT systems were commissioned in 2021. The cumulated number of PVT systems in operation at the end of 2021 was 34,000 representing a total collector area of 1.4 million m² (751 MW_{pb}, 254 MWpeak).

Market status worldwide in 2020

While only the data of the leading 20 countries is available for 2021, the report includes very detailed 2020 data on 70 countries.

109 million solar thermal systems were in operation by the end of 2020.

The top 3 countries in terms of total installed capacity by the end of 2020 were China, Turkey and the United States.

However, the picture is clearly different when comparing the data on a per capita basis.

The top 10 countries in terms of installed capacity per 1,000 inhabitants are Barbados, Cyprus and Israel.

In 2020 evacuated tube collectors represented 60% of the newly installed capacity, followed by flat plate collectors with 34%.

In a global context, this breakdown is mainly driven by the dominance of the Chinese market, where around 72% of all newly installed collectors in 2020 were evacuated tube collectors, but also by the Indian market, with 88% of newly installed collector area being evacuated tubes.

Nevertheless, it is notable that the share of evacuated tube collectors worldwide decreased from about 82% in 2011 to 60% in 2020, and in the same time, flat plate collectors increased their share from about 15% to 34%.

In Europe, the situation is almost the opposite of that in China, with 71% of all solar thermal collectors installed in 2020 being flat plate collectors. In the medium-term perspective, however, the share of flat plate collectors decreased in Europe from 81% in 2011 to 71% in 2020. Overall, the share of evacuated tube collectors in Europe increased between 2011 and 2020 from 16% to 28%.

Distribution by system type

Pumped systems accounted for 64% of all newly installed systems in 2020, while 36% were thermosiphon systems.

Employment and turnover

Based on a comprehensive literature survey and data collected from detailed country reports, the number of jobs in the fields of production, installation and maintenance of solar thermal systems is estimated to be 380,000 worldwide in 2020.¹

The estimated worldwide turnover of the solar thermal industry in 2020 is \in 17 billion (US\$ 18.7 billion).

Solar house Oberduernbach, Austria Photo: Martin Ruehrnschopf

¹ Background information on the methodology used can be found in the Appendix, Chapter 8.3. **3** Worldwide solar thermal capacity in 2021

As shown in the figure below, the global solar thermal capacity of unglazed and glazed water collectors in operation grew from 62 GW_{th} (89 million m²) in 2000 to 522 GW_{th} (746 million m²) in 2021. The corresponding annual solar thermal energy yields amounted to 51 TWh in 2000 and 425 TWh in 2021 (Figure 2).

In 2021 a total capacity of 21 GW_{th} or 31 million square meters of collector area was installed. The 3% increase in installed collector area was the first after seven years of annual declines.

The solar thermal market increased by **3%0** in 2021

Global solar thermal capacity in operation and annual energy yields 2000-2021

Figure 2: Global solar thermal capacity in operation and annual energy 2000-2021

Global solar thermal capacity in operation [GW_{th}]
 Global solar thermal energy yield [TWh]

Figure 3 shows the annual installed collector capacities and the net additions. The difference between the annually installed collector capacity and the net additions is subtracted from the global solar thermal capacity each year when the assumed statistical lifetime of the collectors of 25 years² is reached.

Environmental effects and contribution to climate goals

The global solar thermal energy yields of all installed solar thermal systems in 2021 correspond to a savings of 45.7 million tons of oil and 147.5 million tons of CO_2 . This shows the significant contribution of solar thermal in reducing global greenhouse gas emissions.

Figure 3: Global capacity in operation [GW_{el}], [GW_{th}] 2021 and annual energy yields [TWh_{el}], [TWh_{th}]

> Total capacity in operation [GW_{th}, GW_{el}] Energy supplied [TWh]

² For details on the lifetime see chapter 5

³ The figures for 2021 are based on the latest market data from Australia, Austria, Brazil, China, Cyprus, Denmark, Germany, Greece, India, Italy, Mexico, Morocco, the Palestinian Territories, Poland, South Africa, Spain, Turkey and the United States, which represent about 95% of the cumulated installed capacity in operation in 2020.

3.1

Solar thermal capacity in relation to the capacity of other renewable energy technologies

The cumulated solar thermal capacity in operation by the end of 2021 was 522 GW_{th}^{3} , following behind wind power's installed capacity of 837 GW_{el} and photovoltaics 942 GW_{el} of installed capacity (Figure 4). Geothermal energy and concentrated solar power (CSP) lag behind these three technologies in installed capacity. The total capacity of geothermal power was 16 GW_{al} .

In terms of energy, solar thermal systems supplied 425 TWh of heat, whereas wind turbines supplied 1,980 TWh and photovoltaic systems 1,138 TWh of electricity.

3.2 China - Developments in the world's largest market

To get an idea of the scale and dominance of the Chinese solar thermal market, it is important to mention that of the 21 GW_{th} global installed capacity in 2021, China accounted for 83% or 18 GW_{th}. This is not a new development. In 2006 China already accounted for 69% of the world's installed collectors (Solar Heat Worldwide (2008)). Seventy-five percent of these installations were small thermosiphon systems installed in the thousands on urban apartment buildings as well as single-family houses.

Since 2006, the Chinese market has fundamentally changed. For example, in 2021, only 26% of all newly installed systems in China were thermosiphon systems, while pumped systems accounted for 74%.

As shown in Figure 5, the number of pumped systems is continuously increasing. This is due to financial incentives that have encouraged northern cities to use renewable energy for space heating and replace traditional fossil fuels to reduce carbon emissions. In addition, several reliable and effective solar district heating demonstration projects have been built in recent years.

Distribution by type of system for installed glazed water collector capacity from 2006 to 2021 in China

Figure 5: Distribution by type of system for installed glazed water collector capacity from 2006 to 2021 in China

Pumped solar heating systems Thermosiphon solar heating systems The application of solar thermal systems has gradually changed from domestic water heating to solar combisystems, solar district heating and industrial process heating. At the same time, the size of systems has increased significantly. A number of measures taken by China's central and local governments to reduce CO_2 emissions have contributed significantly to this development.

Figure 6 shows that the largest share of collector area installed in 2021 was for domestic hot water systems in multi-family dwellings, which accounted for about 63.6% of the installations. These are almost exclusively pumped systems with collector areas up to and over 1,000 square meters.

In single-family homes, domestic hot water systems accounted for 28.1% and solar combi-systems used for hot water and space heating accounted for about 6.1%. The share of other applications (solar process heat, solar air conditioning and solar district heating) was 2.2%.

The following picture shows one of the many Chinese solar combi-systems. An example of solar district heating can be found in chapter 4.2.

Solar combi-system consisting of flat plate collectors and a heat pump for space heating at a nursing home in Guyuan County, Ningxia Photo: Jiangsu Micòe Solar Energy Co. Ltd. China

Solar thermal market development and trends in 2021

Hallwang Event Center, Salzburg Photo: Arch. Schindlmeier As mentioned above, the global solar thermal market grew by 3% in 2021. This was due to the fact that China, by far the largest global market, stabilized and recorded a slight growth of 1%. There were also very positive market developments led by Italy's solid growth of 83%, followed by Brazil (28%), the United States (19%), Greece (18%), Poland (17%) and India (16%).

There was an opposite trend in Denmark due to the collapse of its solar district heating market sector. Here, the market decreased by 45% in 2021. Other traditionally strong markets also reported market declines, Spain (-19%), Austria (-7%) and Cyprus (-5%), as well as South Africa (-12%) and Australia (-3%).

Top solar thermal markets in 2021

Figure 7: Countries with the highest growth rates in 2021

Simple thermosiphon systems are very common in the Sunbelt (between the 20th and 40th degrees of latitude in the northern and southern hemispheres) Photo: AEE INTEC

4.1 Small-scale solar thermal heating systems

Small-scale solar water heating systems and, to a certain extent, solar combi-systems for combined hot water preparation and space heating in single-family houses, apartment buildings, multi-family houses, hotels and public buildings represent about 60% of the world's annual solar thermal installations.

In large parts of Europe and China, solar water heating applications are under increasing competition from photovoltaic systems and heat pumps and have lost market share in recent years. The predominant systems are pumped systems, which often use complex system technology.

The picture is different for thermosiphon systems. In Asia (excluding China), Latin America, Sub-Saharan Africa, and the Mediterranean region, thermosiphon systems are by far the dominant system type. Of the countries in Figure 7 above, thermosiphon systems dominate five out of the seven markets.

Solar district heating system installed in 2019 in the Saga District of Tibet has a capacity of 12.6 MW_{th}, corresponding to 18,000 m² flat plate collectors in combination with a 4,500 m³ pit storage Photo: Shandong Soletks Solar Energy Technology Co. Ltd., China

4.2 Large-scale solar thermal heating systems

In the Scandinavian countries Denmark and Sweden, as well as in Austria, Germany, Spain and Greece, large-scale solar thermal plants connected to local or district heating grids, or installed on large residential, commercial and public buildings have been in use since the early 1980s. It should be noted here that from the early 1980s up to 2016, the large-scale solar plant market was almost exclusively concentrated in Europe.

Denmark dominated the large-scale system market - especially for solar district heating - for about a decade. However, due to a drastic change in energy technology policy and funding conditions, the Danish solar district heating market collapsed in 2020. As a result, in 2020 only one new solar district plant and three extensions were built, and in 2021 only one new system with an 8,013 m² collector area was commissioned in Denmark. The shift in policy and funding led Denmark to slip from first to third place among newly installed large-scale plants in 2021.

China reported twenty system installations in 2021, totaling a collector area of about 151,000 m^2 for district heating and large-scale building applications and accounting for 75% of the global market segment.

France ranked second behind China with 10,600 m² installed in the cities of Narbonne, Pons and Creutzwald.

The fourth place ranking goes to Austria, with one new large-scale system for district heating and one extension added to an existing district heating system in Graz, adding up to 7,950 m². Germany, with one system installed in 2021, ranks fifth (5,691 m²) and Turkey sixth (5,621 m²) with seven large-scale installations installed at hotels, mainly in Antalya.

By the end of 2021, 530 large-scale documented solar thermal systems (>350 kW_{th}, 500 m²) were in operation. The total installed capacity of these systems equaled 1,970 MW_{th}, corresponding to 2.8 million m² collector area.

4.2.1 Solar district heating (SDH) systems

The largest sub-sector of large-scale solar thermal heating systems is solar district heating. By the end of 2021, 299 large-scale solar district heating systems (>350 kW_{th}, 500 m²) with an installed capacity of 1,645 MW_{th} (2.35 million m²) were in operation.

As shown in Figure 9, Denmark leads this market segment in terms of both the number of systems and the installed area. In addition to Denmark (125 systems) and China (41 systems), a number of other countries are showing an increasing interest in this type of plant, as they offer an excellent opportunity for decarbonizing the heat sector in neighborhoods and cities.

Countries to note are Germany (45 systems, some of these with seasonal storage), Sweden (24 systems), Austria (22 systems), Poland and France (with 8 systems each). Outside China and Europe, solar district heating systems are installed in Saudi Arabia, Japan, Kyrgyzstan, Russia (Asia excluding China), the USA, Canada, and South Africa (Figure 9).

Table 1 lists the 20 largest solar district heating systems. By far, the largest system was built in the Danish city of Silkeborg in 2016. It has a collector area of almost 157,000 square meters, corresponding to a capacity of 110 MW_{th}. The table also shows the dominance of Denmark in this market segment, as 15 of the 20 largest systems are in Denmark.

4.2.2

Large-scale systems for buildings in the residential, public and commercial sector

Partial view of the solar installation on Lady Pohamba Hospital in Windhoek, Namibia Photo: AFE INTEC

The second market of interest in the large-scale sector, besides solar district heating, is solar applications for residential, commercial and public buildings. At the end of 2021, around 230 large-scale solar thermal systems (>350 kW_{th}; 500 m²) were supplying heat to residential, commercial and public buildings worldwide. The total installed capacity of these systems is 324 MW_{th} (463,100 m²).

China leads this market segment with 84 installed systems and a capacity of 223 MW_{th}, followed by Turkey with 18 systems and an installed capacity of 14.2 MW_{th}. Latin America is in third place with 16 systems and an installed capacity of around 12 MW_{th}.

In addition to the European countries of Greece, France, Austria, Switzerland, Poland and Spain, a growing number of large-scale systems are being built in Latin America (Brazil, Mexico), the MENA region (Dubai, Jordan, Kuwait, United Arab Emirates) and Asia, excluding China (Cambodia, India, Thailand). These systems are often installed on hospitals, hotels and sports centers.

Large-scale systems for residential, public and commercial buildings Collector area, capacities installed and number of systems by country (2021)

Figure 10: Large-scale systems for residential, public and commercial buildings – capacity, installed collector area and number of systems in 2021

4.3 Solar heat for industrial processes

Solar process heat system for Martini & Rossi with a capacity of 0.42 MW_{th} and equipped with high-vacuum flat plate collectors in Turin, Italy Photo: TVP Solar. Switzerland

Across the globe, interest in solar thermal systems for industrial processes (SHIP) has grown steadily. A number of promising projects undertaken in the last couple of years range from small-scale demonstration plants to large 100 MW_{th} systems.

Many industrial processes demand vast amounts of heat, making this sector a promising market for solar thermal applications. Depending on the temperature level of the needed heat, different types of solar thermal collectors are used – air collectors, flat plate and evacuated tube collectors for temperatures up to 100°C and concentrating solar thermal collectors, such as Scheffler dishes, Fresnel collectors and parabolic troughs for temperatures up to 400°C.

According to a study published by Solrico in early 2022 and a survey by AEE INTEC, at least 78 SHIP plants with a collector area of 51,539 m² (36 MW_{th}) were added in 2021 worldwide, so the number of SHIP projects in operation totals at least 975 systems with an overall installed collector area of 1.23 million m².

For 394 of these systems, more detailed information on the collector area, installed capacity, and type of application and collector can be found in the SHIP database, an online portal operated by AEE INTEC in Austria⁴.

Please note that only systems with a collector area larger than 50 m^2 are included in this report. The report's definition of SHIP can be found in the Appendix, chapter 8.6.

Figure 11 to Figure 15 show the analysis of the 394 systems, which have a total collector area of 1,012,613 m² gross and a thermal capacity of 507 MW_{th}. It is important to note that the data in these four graphs is dominated by the world's largest SHIP plant, the Miraah in Oman, which has a thermal capacity of 300 MW_{th}. and accounts for 59% of the total installed thermal capacity of all 394 documented SHIP applications.

The second largest SHIP application is for a greenhouse in Australia (36.6 MW_{th} copper mine in Chile (27.5 MW_{th}) for their copper winning process. Together, these three plants represent 71% of the total installed thermal capacity.

Figure 11 shows the distribution of the 394 systems in terms of size. The three systems mentioned above exceed 21 MW_{th} of thermal capacity (30,000 m²), 54 systems have installed capacities between 0.7 MW_{th} and 21 MW_{th} (1,000 m² - 29,999 m²), 64 systems have installed capacities between 0.35 and 0.7 MW_{th} (500 – 9,999 m²) and 273 systems are below 0.35 MW_{th} (<500 m²).

Industrial Process Heat: 975 systems with a 1.23 million m² collector area

Parabolic trough collectors installed at Comercial Forrajera de Lagos (COMFOSA) in Mexico Copyright: COMFOSA

As shown in Figure 12, the majority of the solar process heat systems use flat-plate collectors followed by parabolic trough collectors and evacuated tube collectors. Parabolic trough collectors have the highest installed gross area, however, without the Miraah plant, it would rank third.

Figure 13 shows the industry sectors of the 394 systems. The main sectors are mining, food and textile. The food and beverage sector grew again in 2021 and is the dominant sector in terms of number of installed systems. It accounts for 159 systems with an average size of 751 m²gross and 59 MW_{+b} of installed thermal capacity.

The mining industry, which includes two of the three largest systems, is the dominant sector in terms of installed thermal capacity. The 14 systems account for 65% of the total installed thermal capacity.

Number of systems [-]

In the agricultural sector, 31 new plants were documented in 2021. A total of 51 systems with 54 $GW_{_{th}}$ are now confirmed.

Solar wood chip drying with air collectors, Austria Photo: Austria Solar / CONA

Figure 14 documents the global installed solar process heat systems by country. Mexico, Germany and India have the highest number of installed systems, followed by Austria, the USA and Spain. Oman leads in terms of installed thermal capacity with its single installed system.

Table 2 documents all SHIP systems with a collector area greater than 5,000 m², corresponding to 3.5 MW_{++} .

Solar heated greenhouses

In addition to the more traditional industrial sectors that use thermal solar systems highlighted above, a new sector is horticulture. Solar thermal plants are being used to heat greenhouses for flower and vegetable cultivation.

The following table provides an overview of the systems with collector areas larger than 50 \mbox{m}^2 between 2013 and 2020.

Table 3: Solar thermal systems for flower and vegetable cultivation

4.4 PVT – Photovoltaic Thermal Systems

Photovoltaic-Thermal (PVT) collectors combine the production of both types of solar energy – solar heat and solar electricity – simultaneously in one collector, thus reaching higher yields per area. This is particularly important if the available roof area is limited, but integrated solar energy concepts are needed to achieve a climate-neutral energy supply for consumers, such as in residential and commercial buildings.

The technology is somewhat more complex than just a PV or a solar thermal collector but provides significant advantages. The PV output can be slightly higher if the collectors are operated at temperatures below those of a PV-only module. Depending on the type of PVT collector, the produced temperature ranges from about -20°C up to +150°C and serves a wide range of applications. The solar thermal energy generated by a PVT system offers a lot of flexibility in the system design. The energy can be stored in many ways, including onsite tanks, aquifers, ground strata **1.4** million m² PVT collector area installed worldwide

and pit storage systems. It can be used directly for hot water or space heating or for a secondary system such as a heat source (heat pumps). Cooling (radiative and convective) can also be provided directly during the night using the PVT collector's thermal absorber or indirectly through a machine driven by the PV electricity.

Global interest in PVT systems has grown steadily over the past years, leading to many specialized PVT technology suppliers entering the European market.

General market overview

The PVT data is based on a survey of 38 PVT collector manufacturers and PVT system suppliers in 14 different countries.

In 2021, the total installed PVT collector area was 1,442,596 m² (751 MW_{th},254 MW_{peak}). The vast majority of this collector area was installed in Europe (884,329 m²), followed by Asia excluding China (307,540 m²) and China (142,926 m²), which together accounted for 668 MW_{th}, 226 MW_{peak} of the total installed capacity. The remaining installed collector area was shared between the MENA countries (Egypt, Israel and Iraq (68,626 m²)), the Sub-Sahara African countries (Ghana, Lesotho and South Africa (22,926 m²)), the United States and Canada (8,125 m²), Australia (3,576 m²), Latin America (637 m²) and others (3,910 m²).

In the European market, France is the market leader with an installed collector area of 598,157 m², followed by Germany with 127,640 m² and the Netherlands with 91,754 m². In Spain, Italy and Switzerland, collector areas range between 15,000 m² and 20,500 m². In the remaining European countries, collector areas of at least 15,146 m² were reported.

Table 4 shows the cumulated installed collector area by PVT collector type at the end of 2021.

Market development of PVT collectors between 2017 und 2021

Based on data from the 38 PVT manufacturers, the market for PVT collectors saw a constant growth of 9% on average between 2017 and 2020. In 2021, the global market grew by around 13%.

This positive trend also was observed in the European market with an even higher growth rate of 21%, which corresponds to an increase of the yearly new installed capacity of 79,8 MW_{th} and 27,6 MW_{neek}.

The Evropean PVT market grew by **210/0**

Global market development of PVT collectors from 2017 to 2021

By the end of 2021, PVT collectors' total cumulative thermal capacity was 751 MW_{th}, and the PV power was 254 MW_{peak}. With a global share of 60% of installed thermal capacity, uncovered PVT water collectors

were the dominating PVT technology, followed by air collectors with 37% and covered PVT water collectors with 3%. Evacuated tube collectors and concentrators play only a minor role in the total numbers.

SHWW 28 29

Distribution by type of application

In 2021, suppliers of PVT technology commissioned at least 6,036 new PVT systems worldwide. As a result, the cumulated number of PVT systems in operation at the end of 2021 was 33,956. The breakdown is 77.2% used for solar air(pre)heating/ cooling buildings, followed by 9.5% for solar combisystems that supply heat for both domestic hot water and space heating and 8.9% for domestic hot water preparation for single-family houses. Around 1.6% of the worldwide installed capacity provided heat and electricity to large domestic hot water systems for multifamily buildings, hotels, hospitals, schools, etc. The remaining systems account for around 5.4% and deliver heat and electricity to other applications, including swimming pool heating, district heating applications and solar heat for industrial applications.

Table 6 shows PVT systems by application.

Table 6: PVT systems by application

PVT-Applications	Number of installations [#]	Total collector area [m²] - 2021
Swimming pool heating	313	25,406
Domestic hot water systems SFH	3,030	95,032

(Source: AEE INTEC)

As shown in Figure 17 below, solar air systems dominate the PVT market. In a global context, this distribution is mainly driven by the dominance of the French market, where almost all of the manufactured PVT collectors are air collectors. Nevertheless, uncovered water-based PVT collectors are the most common technology.

By the end of 2021, 9,039 systems with uncovered

PVT collectors were in operation, corresponding to a gross area of 844,544 m². Of these systems, 36% were used for domestic hot water preparation in single and multifamily houses, hotels, and hospitals. Around 35% of the systems supplied heat and electricity to households and electric heating elements for domestic hot water and space heating (combi-systems).

4.5.1 Small and medium-size applications

The global market for cooling and refrigeration will continue to grow, particularly in emerging countries, and by 2050 37% of the total electricity demand growth will be due to the electricity demand for air conditioning⁵. Thus, there is enormous potential for cooling systems that use solar energy, both solar thermal and PV driven solar cooling and air conditioning systems, as presented, for example, in the GIZ 2017 feasibility study for social housing buildings in Mexico⁶ and the RCREEE/UNDP 2015 study on commercial buildings/applications in the Arab region⁷. A major argument for using solar thermally driven systems is that they consume less conventional energy (up to factor five⁸) and use natural refrigerants, such as water and ammonia. In Europe, their application is also pushed by the European F-gas Regulation No. 517/2014. Another driver for solar cooling technology is its potential to reduce peak electricity demand, particularly in countries with significant cooling needs with grid constraints. Today, for example, 30% of India's total energy consumption in buildings is used for space cooling and reaches up to 60% of the summer peak load, and is already stretching the capacity of the Indian national electricity supply⁹. In other countries, like the USA, the peak load through air conditioning reaches >70% on hot days.

These mature cooling technologies are grabbing the attention of the OECD and emerging countries because cooling demand will continue to grow over the next decades and national electric grids need protection against overloads.

⁹ Low energy cooling and ventilation in indian residences, https://doi.org/10.1080/23744731.2018.1522144

Solar sorption cooling applications are particularly adapted for medium to large size units (100 kW to several MWs). For several years now, China has been promoting a voluntary policy to develop such green sorption devices. And in 2019, Germany changed its incentives scheme for both vapor compression and sorption-based technologies to only support chillers and air conditioners that use natural refrigerants (sorption chillers 5 kW - 600 kW) in combination with a minimum required performance¹⁰.

Solar thermal cooling is still a niche market, with more than 2,000 systems deployed globally as of 2021. And due to changing distribution channels and B2B sales of the sorption chillers, the tracking of newly installed solar-driven systems is difficult and can only be estimated. Small units with a capacity lower than 20 kW are getting more compact (and thus cheaper upfront costs) and targeting the mass markets. Medium to large-scale projects, 350 kW -2,000 kW, are dominated by engineered systems. Of the small and medium capacity (<350 kW) solar cooling systems worldwide, 70% are installed in Europe. According to a survey carried out in early 2019 by SOLRICO for REN21¹¹, only a small number of new solar cooling systems in the small and medium range were installed in 2018, mainly in Italy and Germany. However, awareness of small to mediumscale solar thermal driven systems is rising, and there are several international initiatives (e.g., MI IC7, K-CEP, IEA SHC Programme, etc.), research projects (e.g., SunbeltChiller, HyCool¹², sol.e.h.²¹³, Zeosol¹⁴, etc.) and commercial solar thermal cooling projects (e.g., China, Spain, the USA, Egypt, Mali, Greece, Austria, Africa and Thailand).

4.5.2 Solar Cooling with a cooling capacity larger than 350 kW

Solar cooling using thermal absorption chillers with a cooling capacity larger than 350 kW/100 RT¹⁵ has improved significantly in performance and, at the same time, decreased in cost. In addition, there have been significant improvements in the performance of large flat plate collectors at temperatures up to 120°C. This increase in performance combined with an economy of scale makes solar cooling applications cost-competitive for large office buildings, hotels, hospitals, and commercial/industrial applications.

The advantage of solar energy for cooling is that the supply, solar radiation, is available when the demand, cooling, is at its peak. In other words, cooling is needed when the sun is shining, which means during peak demand. Solar cooling saves money by avoiding the need to purchase electricity at its highest cost. Plus, solar thermal energy is an easy way to store the solar heat and shift it for cooling demands in the evenings and nights while keeping the remaining energy for morning cooling.

The electricity needed by a solar cooling system to run pumps and the cooling tower is relatively low. Depending on the climate, it may give Energy Efficiency Ratios (kW_{th}/kW_{el}) of 20 to 40 in systems with optimized variable speed-driven auxiliaries. Thus, the electric demand for air conditioning in a building is cut by more than 80% compared to conventional HVAC equipment.

Even though the technical and economic conditions for solar cooling and air conditioning have improved significantly, this remains a challenging market, as reflected in the comparatively low number of solar cooling systems built in recent years.

The world's largest solar cooling application is located in Arizona, USA, and was commissioned in May 2014. The installation covers a roof-mounted solar thermal collector field with a capacity of 3.4 MW_{th} (4,865 m²) that supplies heat to a single-effect lithium bromide absorption chiller with a cooling capacity of 1.75 MW.

Four other large solar cooling systems were installed in 2018; two systems in Italy and one in Singapore, all of which use evacuated tube collectors, and one system in Jordan that uses Fresnel collectors to provide the heat for the chiller.

In 2020, two larger solar cooling plants were commissioned. One is a plant with 660 kW cooling capacity in Graz, Austria, and the second plant is in the UAE.

Unfortunately, not a single large-scale new solar cooling system was commissioned in 2021.

4.5.3 Trends and outlook

The demand for cooling and refrigeration will continue its rapid growth, particularly in emerging countries (several hundred million AC units are estimated to be sold per year by 2050¹⁶). This means there is a huge potential for cooling systems that use solar energy – thermal systems and photovoltaic (PV) systems.

The trend regarding solar cooling can be seen in Table 7. In the past 13 years, very few large installations were realized each year. A change in this trend is not foreseeable at present. Despite the potential presented in many studies, it will not be possible to exploit it until system prices and complexity are significantly reduced. Furthermore, it must, unfortunately, be noted that only a very few specialized companies are currently dealing with this topic. It is, therefore, the hope that IEA SHC Task 65 will provide the needed impetus through its joint research and development efforts.

4.6 Solar air heating systems

Solar air heating systems are designed to heat air directly for applications requiring warm air. The primary uses for solar air heaters are heating of buildings, including ventilation air, and process or crop drying systems. Solar air heating is currently an under-utilized solar technology. The recent COVID requirements to increase fresh air in buildings will increase energy demand and CO_2 emissions, and solar heating of this fresh air is an excellent solution to minimize this increased energy demand.

Space heating consumes more energy than hot water in most buildings. In colder climates, space heating is usually the largest energy consumer in a building. As it is the air in a building that is heated, air collectors are ideally suited to heat this air directly without heat exchangers. To take advantage of the lower winter sun angles and eliminate any snow accumulation typical of roof-mounted systems, most solar air collectors used for heating buildings are wall-mounted. When heat is not needed during the summer, the panels are generally left dormant as stagnation temperature is not usually an issue.

Solar air heating systems can be building integrated and typically reduce between 20–30% of the conventional energy used to heat a building. The air is generally taken off the top of the wall, and the heated or pre-heated fresh air is then connected to existing or new fans and ducted into the building via the ventilation system.

Process applications are different as they operate either all year or during the harvest season, allowing the panels to be roof-mounted to capture the higher sun angles.

Solar air heaters in agriculture are primarily for drying applications requiring low temperature.

For the past 30 years, solar air heating systems have been used worldwide by schools, municipalities, military, agricultural, commercial and industrial entities, as well as in residential buildings.

Storage of the heat is possible, but most solar air systems do not include storage to minimize costs.

Toronto Transit Commission (TTC) McNicoll Bus Garage; Toronto, Canada 2,200 m² of black SolarWall air heating systems were integrated into the south and west elevations. The system is used for ventilation heating Photo: SolarWall Conserval Engineering Inc.

The following table lists those countries where more than $10,000 \text{ m}^2$ of solar air collectors are documented.

Table 8: Countries with larger solar air collectormarkets - Total installed air collector areas in 2020

Country	Air Collec	tors [m²]	Total	Installed	
Country	unglazed	glazed	[m²]	capacity [MW _{th}]	
Canada	424,478	52,451	476,929	334	
Australia	250,000	10,000	260,000	182	
Japan		252,787	252,787	177	
United States	127,431	71,000	198,431	139	
United Kingdom	23,600		23,600	17	
Denmark	4,300	18,000	22,300	16	
Germany		18,240	18,240	13	
Turkey	12,570		12,570	9	
India		12,400	12,400	9	
France (mainland)	10,558	1,100	11,658	8	
China	7,700	3,000	10,700	7	

By the end of 2020, 985 MW_{th} (1,405,962 m²) of glazed and unglazed air collectors were installed worldwide. The annual worldwide market in 2020 was in the range of 12 MW_{th} (17,000 m²).

Solar space heating with air collectors is not as common in Europe, while in North America, buildingintegrated solar air collectors are the most popular form of solar thermal systems in the commercial, industrial and institutional markets due to their low cost and architectural integration into buildings. Architects are creative as they integrate solar air heaters into the facades.

Detailed global market data and country statistics in 2020

Energiebunker Wilhelmsburg, Hamburg, Germany Source: Ritter XL Solar, Photographer Oliver Killig

The following chapters of the report provide detailed solar thermal market figures for 2020 and country figures for 70 countries.

Background of the presented data

The figures in the following chapters are the collector area in operation in 2020 and not the cumulated collector area installed in a country, meaning that system lifetimes are considered. To determine the collector area and respective capacity in operation, either official country reports on the lifetime were used or, if such reports were not available, a 25-year lifetime for a system was calculated. The collector area in operation was then calculated using a linear equation. For China, the methodology of the Chinese Solar Thermal Industry Federation (CSTIF) was used until 2018. According to the CSTIF approach, the operation lifetime was 10 years. From 2019 on, an increased lifetime is used to calculate the cumulated collector area accounting for the fact that the share of large systems in China has increased over the past few years. According to this approach, a lifetime of 12 years is used for 2020, increasing to 13 years in 2021. For Germany, a lifetime of 25 years was used in accordance with accumulated market statistic figures for Germany published by BSW¹⁷.

The analysis further distinguishes between different types of solar thermal collectors: unglazed water collectors, glazed water collectors, including flat plate collectors (FPC) and evacuated tube collectors (ETC), and unglazed and glazed air collectors. Concentrating collectors are not within the scope of this report.

5.1

General market overview of the total installed capacity in operation

By the end of 2020, an installed capacity of 500 $\rm GW_{th},$ corresponding to a total of 714 million $\rm m^2$ of collector area, was in operation worldwide.

The vast majority of the total capacity in operation was installed in China (364.0 GW_{th}) and Europe (59.5 GW_{th}), which accounted for 84.7% of the total installed capacity. The remaining installed capacity was shared between the United States and Canada (19.1 GW_{th}), Latin America (17.4. GW_{th}), Asia excluding China (16.6 GW_{th}), the MENA¹⁸ countries Israel, Jordan, Lebanon, Morocco, the Palestinian Territories and Tunisia (7.6 GW_{th}), Australia and New Zealand (6.9 GW_{th}), and the Sub-Sahara African countries Botswana, Burkina Faso, Cape Verde, Ghana, Kenya, Lesotho, Mauritius, Mozambique, Namibia, Nigeria, Senegal, South Africa and Zimbabwe (2.3 GW_{th}). The market volume of "all other countries" is estimated to amount to 5% of the total installations, excluding China (6.8 GW_{th}).

+ Exports excluded
 ++ France overseas calculated based on Eurobserver Reports 2015-2019
 +++ 2021 revised timeseries according to MDPI Switzerland 2021

The total installed capacity in operation in 2020 was divided into flat plate collectors (FPC): 124.2 GW_{th} (177.4 million m²), evacuated tube collectors (ETC): 344.3 GW_{th} (491.9 million m²), unglazed water collectors: 30.7 GW_{th} (43.9 million m²), and glazed and unglazed air collectors: 1 GW_{th} (1.4 million m²).

With a global share of 68.9%, evacuated tube collectors were the predominant solar thermal collector technology, followed by flat plate collectors with 24.8% and unglazed water collectors with 6.1% (Figure 19). Air collectors play only a minor role in the total numbers.

In Europe, the second largest market to China, flat plate collectors were the dominant collector type (Figure 20). Compared to 2019, the share of evacuated tube collectors increased in Europe by 1%, and the share of unglazed water collectors decreased to 2.4% in 2020.

Figure 21 shows the cumulated installed capacity of glazed and unglazed water collectors in operation for the 10 leading markets in 2020 in total numbers.

Figure 19: Distribution of the total installed capacity in operation by collector type in 2020 – WORLD

Figure 20: Distribution of the total installed capacity in operation by collector type in 2020 – EUROPE

Europe: EU 27, Albania, North Macedonia, Norway, Russia, Switzerland, Turkey, United Kingdom

Figure 21: Top 10 countries of cumulated water collector installations in 2020 (absolute figures in MW_{th})

Compared to 2019, the first seven positions remained the same, as did Greece in the ninth position. Mexico moved to the eighth position ousting Austria from this position and the top 10 list. Italy took the tenth position from Israel.

China remained the world leader in total capacity and a market dominated by evacuated tube collectors. The United States held its third position due to its high number of installed unglazed water collectors. Besides the United States, only Australia and, to some extent Brazil, have large numbers of unglazed water collectors installed. In the large European markets, Germany, Austria and Greece, flat plate collectors were the most dominant collector technology. In Turkey, over the past several years, there has been a strong trend toward evacuated tube collector technology. The top 10 countries with the highest market penetration per capita are shown in Figure 21. The leading countries in cumulated glazed and unglazed water collector capacity in operation in 2020 per 1,000 inhabitants were Barbados (600 kW_{th}/1,000 inhabitants), Cyprus (461 kW_{th}/1,000 inhabitants), Israel (398 kW_{th}/1,000 inhabitants), Austria (389 kW_{th}/1,000 inhabitants), Greece (329 kW_{th}/1,000 inhabitants), the Palestinian Territories (274 kW_{th}/1,000 inhabitants), China (259 kW_{th}/1,000 inhabitants), Australia (259 kW_{th}/1,000 inhabitants), China (259 kW_{th}/1,000 inhabitants), Erance (overseas) (227 kW_{th}/1000 inhabitants). Denmark was ousted from the top 10 countries with the highest market penetration (m²/1,000 inhabitants) in 2020.

Figure 22: Top 10 countries of cumulated water collector installations per 1,000 inhabitants in 2020 (relative figures in $kW_{\rm th})$

5.2 Total capacity of glazed water collectors in operation

With 363.9 GW_{th} , China was again the overriding leader in terms of total installed capacity of glazed water collectors in 2020. Turkey, Germany, and India have installed capacities between 20 GW_{th} and 10 GW_{th} . (Figure 23).

In terms of total installed capacity of glazed water collectors in operation per 1,000 inhabitants, there was a continued dominance by five countries: Barbados, Cyprus, Israel, Austria and Greece. China ranks seventh in terms of market penetration. Nevertheless, it is remarkable that China, with its 1.37 billion inhabitants, exceeds the solar thermal per capacity levels of the large European markets in Germany, Turkey, Denmark and Spain (Figure 24).

Cumulated capacity of glazed water collectors in 2020 per 1,000 inhabitants

5.3 Total capacity of glazed water collectors in operation by economic region

Cumulated capacity of glazed water collectors in 2020 by economic region

Figure 27: Total capacity of glazed flat plate and evacuated tube collectors in operation by economic region in 2020

In terms of market penetration per capita by economic region, China again takes the lead. Remarkably, the MENA countries and Australia are ahead of Europe, which only confirms the very unbalanced market distribution in Europe (Figure 28). Whereas some European countries like Cyprus, Austria and Greece belong to the world market leaders in terms of high market penetration, others like the Baltic countries have negligible solar thermal market penetration. Cumulated capacity of glazed water collectors in 2020 per 1,000 inhabitants by economic region

5.4 Total capacity of unglazed water collectors in operation

Unglazed water collectors are mainly used for swimming pool heating. This type of collector has lost a significant market share over the past decade. The percentage of unglazed water collectors in the total installed collector capacity was reduced from 21%¹⁹ in 2005 to just 6% in 2020. Figure 30 and Figure 31 show the total installed capacity of unglazed water collectors and total installed capacity of unglazed water collectors per 1,000 inhabitants at the end of 2020.

5.5 Newly installed capacity in 2020 and market development

In 2020, a total capacity of 24.7 $\rm GW_{th},$ corresponding to 35.3 million $\rm m^2$ of new solar collectors, was installed worldwide.

The main markets were in China (17.5 GW_{th}) and Europe (2.8 GW_{th}), which accounted for 82.3% of all new collector installations in 2020. The rest of the market was shared between Latin America (1.4 GW_{th}), Asia excluding China (1.2 GW_{th}), the United States and Canada (0.5 GW_{th}), MENA countries (0.4 GW_{th}), Australia (0.4 GW_{th}), and Sub-Sahara African countries (0.1 GW_{th}). The market volume of "all other countries" is estimated to amount to 0.4 GW_{th} (511,000 m²).

Note: If no data is given: no reliable database for this collector type is available. * 0% growth assumed ** estimation

New installations in 2020 are divided into flat plate collectors: 8.4 GW_{th} (11.9 million m²), evacuated tube collectors: 14.8 GW_{th} (23 million square meters), unglazed water collectors: 1.5 GW_{th} (2.1 million m²), and glazed and unglazed air collectors: 0.01 GW_{th} (0.017 million m²).

With a share of 60.0%, evacuated tube collectors remain the most important solar thermal collector technology worldwide (Figure 32).

In a global context, this breakdown is mainly driven by the dominance of the Chinese market, where around 72% of all newly installed collectors in 2020 were evacuated tube collectors. Nevertheless, it is notable that the share of evacuated tube collectors decreased from about 82% in 2011 to 60.0% in 2020 while in the same time frame flat plate collectors increased their share from 14.7% to 34.0%. In Europe, the situation is almost the opposite of China, with 71.5% of all solar thermal collectors installed in 2020 being flat plate collectors (Figure 33). In the medium-term perspective, the share of flat plate collectors decreased in Europe from 81.5% in 2011 to 71.5% in 2020. While driven mainly by the markets in Turkey, Poland, Switzerland and Germany, evacuated tube collectors increased their share in Europe between 2011 and 2020 from 15.6% to 28.1%.

Figure 32: Distribution of newly installed capacity by collector type in 2020 – WORLD

Figure 33: Distribution of newly installed capacity by collector type in 2020 – EUROPE

Europe: EU 27, Albania, North Macedonia, Norway, Russia, Switzerland, Turkey, United Kingdom

Figure 34 shows the newly installed capacity of glazed and unglazed water collectors for the 10 leading markets in 2020 in total numbers. China remained the market leader in absolute terms, followed by Turkey and India. Brazil and the United States rank four and five in absolute numbers and are ahead of Germany and Australia. Mexico, Israel and Greece are within the top 10 countries, ranking eighth to tenth.

Newly installed capacity of water collectors 2020: Top 10 Countries (absolute)

unglazed water collectors evacuated tube collectors

In terms of newly installed water collectors capacity per 1,000 inhabitants in 2020, the top 10 countries are shown in Figure 35.

Cyprus, Barbados, Israel and Greece rank first to fourth in 2020, like the year before. France (overseas)

takes the fifth place from Denmark, which is no longer in the top 10. Turkey, Australia and China rank sixth to ninth, the Palestinian Territories take the ninth place and Austria ranks tenth.

flat plate collectors

Newly installed capacity of water collectors 2020: Top 10 Countries (per 1,000 inhabitants)

Figure 35: Top 10 markets for glazed and unglazed water collectors in 2020 (in kW_{th} per 1,000 inhabitants)

5.6 Newly installed capacity of glazed water collectors

In 2020, glazed water collectors accounted for 94% of the total newly installed capacity. China was the most influential market in the global context (Figure 36).

Figure 36: Newly installed capacity of glazed water collectors in 2020

In terms of newly installed glazed water collector capacity per 1,000 inhabitants, Cyprus is again the leader, ahead of Israel and Barbados. In this respect, China ranks in eighth place (Figure 37).

Newly installed capacity of glazed water collectors in 2020 per 1,000 inhabitants

Figure 37: Newly installed capacity of glazed water collectors in 2020 in kW_{th} per 1,000 inhabitants

The following figures show the solar thermal market penetration per capita of the newly installed capacity in 2020 worldwide and in Europe.

Figure 38: Newly installed capacity in 2020 in kW_{th} per 1,000 inhabitants – WORLD (Source: Natural Earth v.4.1.0, 2020/ AEE INTEC).

Figure 39: New Installed capacity in 2020 in kW_{th} per 1,000 inhabitants – EUROPE (Source: Natural Earth v.4.1.0, 2020/ AEE INTEC)

5.7 Market development of glazed water collectors between 2000 and 2020

The worldwide market of glazed water collectors was characterized by a steady upward trend between 2000 and 2011 and then leveled off in 2012 and 2013 at around 50 GW_{th}. In 2014, a significant market decline of -15.6% was reported for the first time since 2000. This trend continued with slightly recovering markets in 2017 and 2018, but 2019 saw a 16% decline, recovering again in 2020 with minus 6%. The newly installed glazed water collector capacity in

The newly installed glazed water collector capacity in 2020 amounted to 23.2 GW $_{\rm th}$ (Figure 40).

In 2000, the Chinese market was about three times as large as the European market, and by 2020, the Chinese market exceeded the European market by about six-fold (Figure 41).

Figure 41 also shows that after years of very high growth rates in China, this trend has changed in

the past years. Compared to the years before, the Chinese market began to experience low growth rates in 2012 and 2013 and then shrank significantly in 2014 and 2015. However, this downward trend became less dramatic from 2015 to 2020.

Annual installed capacity of glazed water collectors 2000 - 2020 China and Europe

Figure 41: Market development of glazed water collectors in China and Europe 2000-2020

The European market peaked at 4.4 GW_{th} installed capacity in 2008 and has decreased steadily down to 2.8 GW_{th} in 2017, showed a slight recovery in 2019, and went again down to 2.8 GW_{th} in 2020. In the "remaining markets worldwide" (RoW), an upward

trend could be observed between 2002 and 2012 and a falling trend from 2013 to 2016. In 2016 a slight upward trend was noticeable but declined again in 2020 (Figure 42).

Figure 42: Market development of glazed water collectors in Europe and the rest of the world (RoW, excluding China) from 2000 to 2020

Europe: EU 27, Albania, North Macedonia, Norway, Russia, Switzerland, Turkey, United Kingdom Rest of World (RoW): Asia (Bhutan, India, Japan, South Korea, Taiwan, Thailand), Australia, Canada, United States Latin America (Argentina, Brazil, Chile, Mexico, Uruguay)

Nigeria, Senegal, South Africa, Zimbabwe),

Capacity [GW_{th}]

"All other countries" see figures for 2020 in Tables 4 and 5

Rest of the World (RoW) includes all economic regions other than China and Europe. Of these regions, Asia (excluding China), Latin America and the MENA countries hold the largest market shares (see Figure 43).

"Asia excl. China" is mainly influenced by the large Indian market, which dropped in 2013 but recovered significantly in 2014 and 2015. After a drop again in 2016, it shows an upward trend. Other markets covered within this economic region are Japan and South Korea.

Latin America showed the most steady and dynamic upward trend of all the economic regions until 2014. The dominant Brazilian market and the large Mexican market plus the evolving markets, for example, in Chile, are responsible for the positive growth rates over the past six years. Since 2015, the market in this region has been stable, with slight decreases in 2017 and 2018 but recovering again in 2019 and 2020. Glazed water collector markets in the MENA countries saw steady growth from 2000 to 2013. The market decline since 2014, shown in Figure 43, is explained by the fact that from 2015 on, there was no data for one of the major markets - Jordan. The sales numbers in the most important market, Israel, slightly decreased in 2020.

Europe 🗕 RoW*

The market volume for glazed water collectors in Australia was similar to that in Latin America and the MENA countries in 2009 but began to shrink more or less through 2015. In 2020, the market showed a 2% decrease.

Sub-Sahara African markets were stable in 2020. In the United States and Canada, the decreasing trend continued with a significant decline in 2020.

Annual installed capacity of glazed water collectors 2000 - 2020 Europe and RoW

Asia excl. China: Bhutan, India, Japan, Korea South, Taiwan, Thailand Latin America: Argentina, Brazil, Chile, Mexico, Uruguay MENA countries: Israel, Jordan, Lebanon, Morocco, Palestinian Territories, Tunisia Sub-Sahara Africa: Botswana, Burkina Faso, Cape Verde, Ghana, Kenya, Lesotho, Mauritius, Mozambique, Namibia, Nigeria, Senegal, South Africa, Zimbabwe

In relative figures, the annual global market volume for glazed water collectors grew from 1.2 kW_{th} per 1,000 inhabitants in 2000 to 7.0 kW_{th} per 1,000 inhabitants in 2013 and dropped down to 3.0 kW_{th} per 1,000 inhabitants in 2020 (Figure 44).

Capacity [kW_{th} per 1,000 inh.]

Annual installed capacity of glazed water collectors 2000 - 2020

Figure 44: Annual installed capacity of glazed water collectors in $kW_{\rm th}$ per 1,000 inhabitants from 2000 to 2020

The fact that China suffered major market declines from 2014 to 2016 is also reflected in the market penetration of glazed water collector installations per capita. The annually installed capacity rose from $3.5 \text{ kW}_{\text{th}}$ per 1,000 inhabitants in 2000, peaked at $32.2 \text{ kW}_{\text{th}}$ per 1,000 inhabitants in 2013 and fell to 12.5 kW_{th} per 1,000 inhabitants in 2020.

In Europe, market penetration peaked in 2008 at 5.9 kW_{th} per 1,000 inhabitants. The downward trend between 2009 and 2013 seems to have stabilized from 2014 on and lies at 3.6 kW_{th} per 1,000 inhabitants in 2020.

5.8

Market development of unglazed water collectors between 2000 and 2020

With a newly installed capacity of 1.5 $\rm GW_{th}$ in 2020, unglazed water collectors accounted for 5.9% of the total installed solar thermal capacity (Figure 32). Compared to 2019, the market was stable.

The most important markets for unglazed water collectors in 2020 were the United States (473 MW_{th}), Brazil (498 MW_{th}) and Australia (266 MW_{th}). Mexico reported 75 MW_{th} installed unglazed water collector area and South Africa 40 MW_{th}. The capacity in these countries accounted for 93% of the recorded unglazed water collector installations worldwide. Switzerland (2.6 MW_{th}), Spain (2 MW_{th}) and the Netherlands (1.8 MW_{th}) also reported unglazed water collector installations in 2020.

Solar system for outdoor pool Obersulm, Germany Photo: AST Eis- und Solartechnik GmbH, Austria

The unglazed water collector market in the United States peaked in 2006 (1.01 GW_{th}) and has about halved since then (0.47 GW_{th} in 2020). Nevertheless, the annual global market volume for unglazed water collectors has remained nearly constant because of the Brazilian market, which entered in 2007 and peaked in 2014 at 0.45 GW_{th}. Australia has faced a market decline since 2010 and is now the third largest market for unglazed water collectors behind that of the United States and Brazil.

Contribution to the energy supply and CO₂ reduction in 2020

In this section, the total installed glazed and unglazed water collectors' contribution to the thermal energy supply and CO, reduction is detailed.

The annual collector yield of all water-based solar thermal systems for the simulated applications (swimming pool, DHW for single-family houses, DHW for multi-family houses and solar combi-systems) in operation at the end of 2020 in the 70 recorded countries was 406 TW_h (= 1,460 PJ). This corresponds to a final energy savings equivalent of 43.6 million tons of oil and 137.9 million tons of CO₂. The calculated number of solar thermal systems in operation was around 108 million (Table 13). The CO₂ emissions saved by the thermal solar systems in operation in 2020 were about 138 million t/a or 3.2 times the CO₂ emissions of Switzerland²⁰.

²⁰ https://de.statista.com/statistik/daten/studie/961158/umfrage/ treibhausgas-emissionen-in-der-schweiz/ The basis for these calculations is the total glazed and unglazed water collector area in operation in each country, as shown in Table 10. The 1.0 GW_{th} contribution of the total installed air collector capacity in operation in 2020 was not taken into consideration – with only a share of around 0.2% of the total installed collector capacity; these collectors were omitted from the calculation.

The results are based on calculations using the simulation tool, T-SOL expert 4.5, for each country. For the simulations, different types of collectors and applications and characteristic climatic conditions were considered for each country. A more detailed description of the methodology can be found in the Appendix (see Chapter 8).

- * Total capacity in operation refers to the year 2014
- ** Total capacity in operation refers to the year 2015
- *** Total capacity in operation refers to the year 2009
- **** Total capacity in operation refers to the year 2016
- + The figures for France relate to mainland France only, overseas departments and regions are not considered.
- ++ For France overseas no collector yield was calculated because of different reference climates

Table 13 summarizes the calculated annual collector yields and the corresponding oil equivalents and CO² reductions of all water-based solar thermal systems in 2020.

Distribution of systems by type and application in 2020

The use of solar thermal energy varies significantly from region to region and can be roughly distinguished by the type of solar thermal collector used (unglazed water collectors, evacuated tube collectors, flat plate collectors, glazed and unglazed air collectors, concentrating collectors), the type of system operation (pumped solar thermal systems, thermosiphon systems) and the main type of application (swimming pool heating, domestic hot water preparation, space heating, others such as heating of industrial processes, solar district heating or solar thermal cooling).

7.1 Distribution by type of solar thermal collector

In terms of the total water collector capacity worldwide in 2020, evacuated tube collectors dominated with 69% of the cumulated capacity in operation (Figure 46) and a share of 60% of the newly installed capacity (Figure 47). Worldwide flat plate collectors accounted for about 25% of the cumulated capacity in operation (Figure 46) and a 34% share of the newly installed capacity (Figure 47). Unglazed water collectors accounted for 6% of both the cumulated water collectors installed worldwide and the newly installed capacity.

In China, evacuated tube collectors are the dominant collector type. In North America, Australia and Sub-Sahara Africa (mainly driven by South Africa) unglazed water collectors represent the largest share. In the other regions, flat plate collectors are dominant. Distribution by type of solar thermal collector for the total installed water collector capacity in operation by the end of 2020

for the total installed water collector capacity in operation by the end of 2020

Sub-Sahara Africa: Botswana, Burkina Faso, Cape Verde, Ghana, Kenya, Lesotho, Mauritius, Mozambique, Namibia,

Nigeria, Senegal, South Africa, Zimbabwe

Asia w/o China: Bhutan, India, Japan, South Korea, Taiwan Thailand

Latin America: Argentina, Barbados, Brazil, Chile, Mexico, Uruguay

Europe: EU 27, Albania, North Macedonia, Norway, Russia, Switzerland, Turkey, United Kingdom

MENA countries: Israel, Jordan, Lebanon, Morocco, Palestine, Tunisia

The distribution of the newly installed collector area is shown below. Evacuated tube collectors are dominant in China and Asia (excluding China), driven by development in India and the increasing share in Sub-Sahara Africa. Unglazed collectors are dominant in North America and Australia. Flat plate collectors dominate in Latin America, Europe and the MENA region.

MENA countries: Israel, Jordan, Lebanon, Morocco, Palestinian Territories, Tunisia

Thermosiphon systems in Mozambique Photo: AEE INTEC

7.2 Distribution by type of system

Worldwide, about 58% of all solar thermal systems installed are thermosiphon systems and the rest are pumped solar heating systems (Figure 48).

Similar to the distribution by type of solar thermal collector in total numbers, the Chinese market influenced the overall figures the most. 26% of all newly installed systems in China were thermosiphon systems, while pumped systems accounted for 74%. The share of thermosiphon systems has been decreasing for several years in China (Figure 49).

In general, thermosiphon systems are more common in warm climates, such as in Africa, South America, southern Europe and the MENA countries. In these regions, thermosiphon systems are more often equipped with flat plate collectors, while in China, the typical thermosiphon system for domestic hot water preparation is equipped with evacuated tubes. Distribution by type of system for the total installed glazed water collector capacity in operation by the end of 2020

7.3 Distribution by type of application

The newly installed water-based solar thermal collector area amounted to 35.3 million m^2 , corresponding to 24.7 GW_{4b} of thermal peak capacity (Table 11).

The largest share of the collector area installed in 2020 is large domestic hot water systems for multi-family houses, tourism and the public sector. Domestic hot

water systems in single-family houses accounted for about 35% of installations in 2020. The share of swimming pool heating was 6%. The share for other applications, such as solar district heating and solar process heat, is about 2% globally (Figure 50).

Appendix

8.1 Methodological approach for the energy calculation

To obtain the energy yield of solar thermal systems, the oil equivalent saved and the CO_2 emissions avoided, the following procedure was used:

- Only water collectors were used in the calculations (unglazed water collectors, flat-plate collectors and evacuated tube collectors). Air collectors were not included.
- For each country, the cumulated water collector area was allocated to the following applications (based on available country market data):
 - Solar thermal systems for swimming pool heating
 - Solar domestic hot water systems for single-family houses,
 - Solar domestic hot water systems for multi-family houses, tourism sector and public sector (to simplify the analysis, solar district heating systems, solar process heat and solar cooling applications were also allocated here), and
 - Solar combi-systems for domestic hot water and space heating for single- and multi-family houses.
- Reference systems were defined for each country and each type of application (pumped or thermosiphon solar thermal system).
- The number of systems per country was determined from the share of collector area for each application and the collector area defined for the reference system.

Apart from the reference applications and systems mentioned above, reference collectors and reference climates were determined. Based on these boundary conditions, simulations were performed using T-Sol [T-Sol, Version 4.5 Expert, Valentin Energiesoftware, www.valentin-software.com] and gross solar yields for each country and system were obtained. The gross solar yields refer to the solar collector heat output and do not include heat losses through transmission piping or storage heat losses²¹.

The amount of final energy saved is calculated from the gross solar yields considering a utilization rate of the auxiliary heating system of 0.8. Final energy savings are expressed in tons of oil equivalent (toe): 1 toe = $11,630 \text{ kW}_{\text{b}}$.

Finally, the CO_2 emissions avoided by the different solar thermal applications are quoted as kilograms carbon dioxide equivalent (kg_{co2e}) per tons of oil equivalent: 1 toe = 3.228 t CO2e²². The emission factor only accounts for direct emissions.

To obtain an exact statement about the CO_2 emissions avoided, the substituted energy medium would have to be ascertained for each country. Since this could only be done in a very detailed survey, which goes beyond the scope of this report, the energy savings and the CO_2 emissions avoided relate only to fuel oil. It is obvious that not all solar thermal systems just replace systems running on oil. This represents a simplification since gas, coal, biomass or electricity can be used as an energy source for the auxiliary heating system instead of oil.

The following tables describe the key data of the reference systems in the different countries, the location of the reference climate used and the share of the total collector area in use for the respective application²³. Furthermore, a hydraulic scheme is shown for each reference system.

²¹ Using gross solar yields for the energy calculations is based on a definition for Renewable Heat by EUROSTAT and IEA SHC. In editions of this report prior to 2011 solar yields calculated included heat losses through transmission piping and hence energy savings considered were about 5 to 15 % less depending on the system, the application and the climate.

²² Source: Carbon trust, Conversion factors Energy and carbon conversion, updated 2016

²³ For some countries no specific estimations are available concerning shares by type of application. In these cases shares given in previous reports were used for the calculation.

8.1.1 Reference systems for swimming pool heating

Table 14 refers to the total capacity of water collectors in operation used for swimming pool heating as reported from each country by the end of 2020.

*Countries not listed in this table did not report any share of collectors used for swimming pool heating.

8.1.2

Reference systems for domestic hot water preparation in single-family houses

The information in Table 15 refers to the total capacity of water collectors in operation used for domestic hot water heating in single-family houses at the end of 2020, as reported by each country.

Figure 51 shows the hydraulic scheme of the swimming pool reference system used to simulate solar energy yields.

Figure 51: Hydraulic scheme of the swimming pool reference system

PS: pumped system TS: thermosiphon system PDS: pumped drain back system

Figure 52 shows the hydraulic scheme used for

Figure 52: Hydraulic scheme of the domestic hot water pumped reference system for single-family houses

Figure 53: Hydraulic scheme of the domestic hot water thermosiphon reference system for single-family houses

For the Chinese thermosiphon systems, the reference system above was used, but instead of a flat plate collector, as shown in Figure 53, a representative Chinese vacuum tube collector was used for the simulation.

8.1.3 Reference systems for domestic hot water preparation in multi-family houses

The information in Table 16 refers to the total capacity of water collectors in operation used for domestic hot water heating in multi-family houses at the end of 2020 as reported by each country.

Figure 54 shows the hydraulic scheme of the domestic hot water reference system for multifamily houses used for the simulations of the solar energy yields. Unlike small-scale domestic hot water systems, all large-scale systems are assumed to be pumped solar thermal systems.

Figure 54: Hydraulic scheme of the domestic hot water pumped reference system for multi-family houses

8.1.4

Reference systems for domestic hot water preparation and space heating in single-family and multi-family houses (solar combi-systems)

The information in Table 17 refers to the total capacity of water collectors in operation used for domestic hot water and space heating in single-family and multifamily houses at the end of 2020, as reported by each country. Table 17: Solar combi-system reference for single-family and multi-family houses and the total collector area in operation in 2020

8.2 Reference collectors

8.2.1

Data of the reference unglazed water collector for swimming pool heating

$$\begin{array}{l} n &= 0.85 \\ a_1 &= 20 \, [W/m^2 K] \\ a_2 &= 0.1 \, [W/m^2 \, K^2] \end{array}$$

8.2.2

Data of the reference collector for all other applications except for China

 $\begin{array}{l} n &= 0.8 \\ a_1 &= 3.69 \, [W/m^2 K] \\ a_2 &= 0.007 \, [W/m^2 \, K^2] \end{array}$

8.2.3

Data of the Chinese reference vacuum tube collector

 $\begin{array}{l} n &= 0.74 \\ a_1 &= 2.5 \, [W/m^2 K] \\ a_2 &= 0.013 \, [W/m^2 \, K^2] \end{array}$

8.3 Methodological approach for the job calculation

The job calculation is based on a comprehensive literature study, information provided by the China National Renewable Energy Centre and IRENA and data collected from different country market reports. Based on this information, the following assumptions were taken to calculate the number of full-time jobs:

In countries with high labor costs, advanced automated production of flat plate or evacuated tube collectors and heat storages – pumped systems with a total of 133 m² solar collector area have to be installed on average per full-time job. Countries with low labor costs and advanced automated production of evacuated tube collectors and heat storages - thermosiphon systems with a total of 87 m² solar collector area have to be installed per full-time job on average. The same collector area has to be installed per full-time job in countries with mainly manual flat plate collector production and low labor cost. For swimming pool systems with unglazed polymeric collector area must be installed per full-time job.

The numbers presented are full-time jobs and consider the production, installation and maintenance of solar thermal systems.

8.4 Reference climates

86 **Definition of SHIP systems**

In November 2019, the IEA Solar Heating and Cooling Programme defined solar heat for industrial processes (SHIP systems). This definition only refers to the collection and documentation of SHIP systems as part of the Solar Heat Worldwide report.

Applications considered as SHIP Systems

Industrial Process Applications

All solar thermal systems, direct or indirect (via heat storage), connected to an industrial process. Systems that, in addition to the industrial process, also supply the space heating for the production halls, offices or showers are taken into account.

Agricultural Applications

Solar thermal systems used for drying wood chips, crops, fruits, etc. and heat for animal breeding.

Greenhouses

Solar thermal systems supplying heat for commercial food and flower production, nurseries and vegetable farming.

Service Sector

Solar thermal systems supplying commercial laundries, car/truck washing, and sewage sludge drying facilities with heat.

Solar cooling of industrial processes

This refers to all cooling processes in industrial plants

Not considered in this definition:

- » Solar air conditioning of office buildings or industry halls
- » Tourism sector like hotels (including laundries of hotels)
- » Health sector: hospitals, clinics
- » Boarding schools
- » Military barracks
- » Showers or canteens for workers

Minimum size of systems

For the worldwide survey, only installations larger than 50 m² are considered. The minimum size of the plants surveyed was determined since small plants in many countries are not recorded separately. This does not mean that there are no SHIP systems with smaller collector areas. In some countries (e.g., Germany), the number of SHIP plants with collector areas below 50 m² is significantly higher than the realized plants above that limit.

8.7 Methodological adjustments and market data of the previous years

Change in the method for estimating global installed capacity

Global solar thermal capacity is based on the latest market data from about 20 of the largest solar thermal markets in terms of added capacity. These were the following countries for the year 2021 listed in order of their added capacity: China, India, Turkey, Brazil, Germany, Greece, Mexico, Italy, Poland, Spain, Australia, South Africa, Cyprus, Austria, United States, Palestinian Territories, Denmark which represented 94.4% of the cumulative installed capacity in operation in 2020. The added capacities in the other countries, for which new additions are available until 2020, were projected according to the trend over the past two years. The rest of the world, which means countries without detailed solar thermal market information in 2020 and previous years, were estimated to be 5% of the global market volume without China in 2020.

Until 2019, the "rest of the world" was considered 5% of the global market, including China, which overestimated its market share. This methodological change should be noted when comparing data from this year's edition of Solar Heat Worldwide with earlier editions.

Conversion from square meters to capacity

The data presented in Chapters 5 to 8 were initially collected in square meters. Through an agreement of international experts, the collector areas of these solar thermal applications have been converted and shown in installed capacity.

Making the installed capacity of solar thermal collectors comparable with that of other energy sources, solar thermal experts from seven countries agreed upon a methodology to convert installed collector area into solar thermal capacity.

The methodology was developed during a meeting with IEA SHC Programme officials and major solar thermal trade associations in Gleisdorf, Austria, in September 2004. The represented associations from Austria, Canada, Germany, the Netherlands, Sweden and the United States as well as the European Solar Thermal Industry Federation (ESTIF) and the IEA SHC Programme, agreed to use a factor of 0.7 kW, /m² to derive the nominal capacity from the area of installed collectors.

Data from the previous years

The following tables provide data from the previous years to ensure consistency of the calculations within this report. If necessary, the numbers have been revised compared to the data published in earlier editions of this report due to changes in methodology or the origin of the data for each country.

In Table 21, Table 22 and Table 23, these countries are marked accordingly and in Chapter 8.8 (References), the respective data source is cited.
